The `term` module is an enhanced version of the standard library's `tty` module. It provides a set of functions and context managers for POSIX-style terminal programming.

See also:

Module `termios`

Low-level terminal control interface.

Xterm Control Sequences

Detailed list of escape sequences accepted by xterm.

API DOCUMENTATION

CONSTANTS

`term.IFLAG = 0`

Input modes. Index into list returned by `tcgetattr`.

`term.OFLAG = 1`

Output modes. Index into list returned by `tcgetattr`.

`term.CFLAG = 2`

Control modes. Index into list returned by `tcgetattr`.

`term.LFLAG = 3`

Local modes. Index into list returned by `tcgetattr`.

`term.ISPEED = 4`

Input speed. Index into list returned by `tcgetattr`.

`term.OSPEED = 5`

Output speed. Index into list returned by `tcgetattr`.

`term.CC = 6`

Control characters. Index into list returned by `tcgetattr`.

`term.TIMEOUT = 2`

The default read timeout in 1/10ths of a second.

TERMINAL CONTROL

`term.setraw(fd, when=TCSAFLUSH, min=1, time=0)`

Put the terminal in raw mode.

Wait until at least *min* bytes or characters have been read. If *min* is 0, give up after *time* (in 1/10ths of a second) without data becoming available.

`term.setcbreak(fd, when=TCSAFLUSH, min=1, time=0)`

Put the terminal in cbreak mode.

Wait until at least *min* bytes or characters have been read. If *min* is 0, give up after *time* (in 1/10ths of a second) without data becoming available.

`term.rawmode(fd, when=TCSAFLUSH, min=1, time=0)`

Context manager to put the terminal in raw mode.

The current mode is saved and restored on exit.

`term.cbreakmode(fd, when=TCSAFLUSH, min=1, time=0)`

Context manager to put the terminal in cbreak mode.

The current mode is saved and restored on exit.

TERMINAL I/O

`term.openpty(bufsize=-1, mode='r+b')`

Context manager returning a new rw stream connected to `/dev/tty`.

The stream is `None` if the device cannot be opened. The *mode* argument must be `'r+b'` (default) or `'r+'`.

`term.readto(stream, endswith)`

Read bytes or characters from *stream* until `buffer.endswith(endswith)` is true.

The *endswith* argument may be a single suffix or a tuple of suffixes to try. Suffixes must be bytes or str depending on the stream. Empty suffixes are ignored.

HIGH-LEVEL FUNCTIONS

These functions are implemented using the low-level facilities above and should probably live in a different package; yet here we are.

All functions may time out if the terminal does not respond. Set `term.TIMEOUT` to increase the timeout.

High-level functions are not included in `from term import *`.

term.getyx()

Return the cursor position as 1-based (line, col) tuple.

Line and col are 0 if the device cannot be opened or does not support DSR 6.

term.getfgcolor()

Return the terminal foreground color as (r, g, b) tuple.

All values are -1 if the device cannot be opened or does not support OSC 10.

term.getbgcolor()

Return the terminal background color as (r, g, b) tuple.

All values are -1 if the device cannot be opened or does not support OSC 11.

term.islightmode()

Return true if the background color is lighter than the foreground color.

May return None if the device cannot be opened or does not support OSC 10 & 11.

term.isdarkmode()

Return true if the background color is darker than the foreground color.

May return None if the device cannot be opened or does not support OSC 10 & 11.

EXAMPLES

The `getyx` function may be implemented like this:

```
from re import search
from term import opentty, cbreakmode, readto

def getyx():
    with opentty() as tty:
        if tty is not None:
            with cbreakmode(tty, min=0, time=2): # 0.2 secs
                tty.write(b'\033[6n') # DSR 6
                p = readto(tty, b'R') # expect b'\033[24;1R'
                if p:
                    m = search(b'(\d+);(\d+)R$', p)
                    if m is not None:
                        return int(m.group(1)), int(m.group(2))
    return 0, 0
```

Or with `stdin/stdout` and text I/O:

```
import sys

from re import search
from term import cbreakmode, readto

def getyx():
    with cbreakmode(sys.stdin, min=0, time=2): # 0.2 secs
        sys.stdout.write('\033[6n')
        sys.stdout.flush()
        p = readto(sys.stdin, 'R') # expect '\033[24;1R'
        if p:
            m = search(r'(\d+);(\d+)R$', p)
            if m is not None:
                return int(m.group(1)), int(m.group(2))
    return 0, 0
```

INDICES AND TABLES

- `genindex`
- `modindex`
- `search`

PYTHON MODULE INDEX

t

term, [1](#)

INDEX

C

`cbreakmode()` (in module *term*), 7
